

# Analysing Algorithms

Daniel Lawson — University of Bristol

Lecture 09.1 (v2.0.0)

# Shall we learn about Turing Machines?

# Questions

- ▶ Can we prove that one algorithm is faster than another?
- ▶ What does  $\mathcal{O}(f(n))$  mean?
- ▶ What is computational complexity?
- ▶ What is the best sorting algorithm? What is “best”?

## Runtime - motivation

- ▶ Consider our algorithm run on data  $D_1$ :
- ▶ Different programming languages/compiler/hardware
- ▶ How do we predict its runtime elsewhere?

# Why study algorithms?

- ▶ Algorithms underlie every machine-learning method.
- ▶ Theoretical statements about algorithms can be made, including:
  - ▶ How long does an algorithm take to run?
  - ▶ What guarantees can be made about the answer an algorithm returns?
- ▶ In some cases, **carefully chosen algorithms** can achieve either perfect or usefully good performance at a vanishing fraction of the run time of a naive implementation.
- ▶ This can lead to a **solution on a single machine** that is superior to that of a massively parallel implementation using distributed computing.

# Algorithmic concerns

- ▶ We typically care about:
  - ▶ How long does the algorithm run for? Under which circumstances?
  - ▶ How do they trade off **runtime** and **memory requirement**?
- ▶ Some special values include **in-place** methods (which have a constant memory requirement) and **streaming** methods which visit the data exactly once each (usually with a constant-sized memory).
- ▶ Proofs typically describe the scaling of these properties, but in practice the constants are very important!

# Algorithmic complexity: Big O Notation

- ▶  $\mathcal{O}(n)$ : An upper bound as a function of data size  $n$
- ▶  $g(n) = \mathcal{O}(f(n))$ :
  - ▶  $\exists n_0, k \in \mathbb{N}$  such that:
  - ▶  $\forall n \geq n_0$ :
  - ▶  $g(n) \leq k \cdot f(n)$

# Algorithmic complexity: Big Omega Notation

- ▶  $\Omega(n)$ : A lower bound a function of data size  $n$
- ▶  $g(n) = \Omega(f(n))$ :
  - ▶  $\exists n_0, k \in \mathbb{N}$  such that:
  - ▶  $\forall n \geq n_0$ :
  - ▶  $g(n) \geq k \cdot f(n)$

# Algorithmic complexity: Big Theta Notation

- ▶  $\Theta(n)$ : A tight bound as a function of data size  $n$
- ▶  $g(n) = \Theta(f(n))$ :
  - ▶  $\exists n_0, k_1, k_2 \in \mathbb{N}$  such that:
  - ▶  $\forall n \geq n_0$ :
  - ▶  $k_1 \cdot f(n) \leq g(n) \leq k_2 \cdot f(n)$
- ▶ i.e. the bound is strict.

# Complexity examples

- ▶  $n \in \mathcal{O}(n^2)$ 
  - ▶  $n \in \mathcal{O}(n)$  as well
  - ▶  $n \in \Omega(n)$
- ▶  $2n^2 + n + 10 \in \mathcal{O}(n^2)$
- ▶  $\log(n) \in \mathcal{O}(n^\epsilon)$  for all  $\epsilon > 0$
- ▶ If  $f(n) \in \mathcal{O}(g(n))$  then  $g(n) \in \Omega(f(n))$
- ▶ If  $f(n) \in \mathcal{O}(g(n))$  and  $f(n) \in \Omega(g(n))$  then  $f(n) \in \Theta(g(n))$
- ▶ If  $f_1(n) \in \mathcal{O}(g_1(n))$  and  $f_2(n) \in \mathcal{O}(g_2(n))$  then  $f_1(n) \cdot f_2(n) \in \mathcal{O}(g_1(n) \cdot g_2(n))$
- ▶ If  $f_1(n) \in \mathcal{O}(g_1(n))$  and  $f_2(n) \in \mathcal{O}(g_2(n))$  then  $f_1(n) + f_2(n) \in \mathcal{O}(\max(g_1(n), g_2(n)))$
- ▶  $2n^2 + 3n + 1 = 2n^2 + \Theta(n) = \Theta(n^2)$

# Algorithmic complexity: Probabilistic Analysis

- ▶ Sometimes we don't want the worst-case behaviour out of all possible inputs
- ▶ In these scenarios **average-case** run time is often reported
  - ▶ This is typically the average over the entire input space
  - ▶ This should make the statistician in you concerned!
- ▶ Randomized algorithms are also important
  - ▶ In these the answer may be random, and take a random amount of time, for a given input!
  - ▶ e.g. MCMC, etc
  - ▶ Again the **expected run time** is often reported
- ▶ We can discuss  $\Theta$ ,  $\Omega$  and  $\mathcal{O}$  of the expected runtime
- ▶ Clearly the distribution of the input data is important
- ▶ Some worst-case scenarios have “measure 0” (i.e. will never occur in practice)

# Complexity and constants

- ▶ Consider the following functions:

```
import time
def constant_fun(n,k):
    time.sleep(k * k);
def linear_fun(n,k):
    for i in range(n):
        time.sleep(1);
```

- ▶ Clearly `linear_fun` is faster for  $n < k^2$ . We need to take into account  $k$  and whether it scales with  $n$ .
- ▶ In practice  $k$  is often truly a constant but can be any scale compared to  $n$ . The accounting therefore needs to retain it.
- ▶ Example: SVD is  $\mathcal{O}(\min(mn^2, m^2n))$
- ▶ Complexity classes **only** describe **asymptotic behaviour** for large  $n$

# Divide and conquer

- ▶ One of the most popular strategies is **Divide and Conquer**, in which we make many sub-problems, each of which is solvable.
- ▶ This is typically valuable for parallelism
- ▶ It also makes sense to apply the algorithm **recursively**.
  - ▶ In which case we obtain expressions like:

$$T(n) = aT(n/k) + D(n) \quad \text{if} \quad n \geq c,$$

- ▶ and  $T(n) = \Theta(1)$  otherwise.
- ▶ This recursion is a relatively straightforward infinite sum (exercises) and leads to  $T(n) = \Theta(n \log_k(n))$

## Other key concepts

- ▶ **Worst case cost** conditions: can require care when looking up the answer.
  - ▶ For example, some data structures have  $\mathcal{O}(n)$  lookup cost if the data are missing, but much better if the data are present.
  - ▶ Also some costs are predictable and rare, leading to. . .
- ▶ **Amortised cost**: The long term, average worst case cost, which is often better than the single case cost.
  - ▶ For example, some data structures must be periodically rebuilt when they get too big, an expensive action. But this is done rarely by construction.

# Algorithm Example (1)

- What is the complexity of the following algorithm?

**procedure** EXAMPLE( $a, b, n$ )

$i \leftarrow 1$

**while**  $i \leq n$  **do**

$a \leftarrow f_1(b, n)$

$b \leftarrow f_2(a, n)$

$i \leftarrow i + 1$

**end while**

**return**  $b$

**end procedure**

- $f_i(a, n)$  has runtime  $T_i(n)$
- Inside loop is  $\mathcal{O}(T_1(n) + T_2(n))$
- Total  $\mathcal{O}[n(T_1(n) + T_2(n))]$

## Algorithm Example (2)

- ▶ Compare to the following algorithm?

**procedure** EXAMPLE( $a, b, n$ )

$i \leftarrow 1$

**while**  $i \leq n$  **do**

$a \leftarrow f_1(b, n)$

$b \leftarrow f_2(a, n)$

$i \leftarrow 2 \cdot i$

**end while**

**return**  $b$

**end procedure**

- ▶ Inside loop is  $\mathcal{O}(T_1(n) + T_2(n))$
- ▶ Total  $\mathcal{O}[\log(n)(T_1(n) + T_2(n))]$

# Sorting examples

- ▶ We have some data: 1, 4, 6, 2, 3, 7, 5,  $\dots$
- ▶ We want to sort the data into ascending order:  
1, 2, 3, 4, 5, 6, 7,  $\dots$
- ▶ What is the best<sup>1</sup> algorithm?
  - ▶ **Insertion sort** is  $\Theta(n^2)$ , but operates in-place.
  - ▶ **Merge sort** is  $\Theta(n \log(n))$ , but memory requirements grow with data size.
  - ▶ **Heap sort** is  $\Theta(n \log(n))$  and sorts in place.
  - ▶ **Quick sort** is  $\Theta(n^2)$ , but  $\Theta(n \log(n))$  expected time, and is often fastest in practice.
  - ▶ **Counting sort** allows array indices to be sorted in  $\Theta(n)$  by exploiting knowledge that all integers are present.
  - ▶ **Bucket sort** is  $\Theta(n^2)$ , though  $\Theta(n)$  average case (if data are Uniform!)

# Quicksort: a Recursion Example

```
procedure QUICKSORT( $A$ )  
  if  $\text{len}(A) == 1$  then  
    return  $A$   
  else  
     $x \leftarrow A$   
     $A_l \leftarrow \{a \in A : a < x\}$   
     $A_h \leftarrow \{a \in A : a >$   
 $x\}$   
     $A_x \leftarrow \{a \in A : a =$   
 $x\}$   
     $S_l \leftarrow \text{QuickSort}(A_l)$   
     $S_h \leftarrow \text{QuickSort}(A_h)$   
    return  $[S_l, A_x, S_h]$   
  end if  
end procedure
```

# Quicksort: a Recursion Example

```
procedure QUICKSORT( $A$ )  
  if  $\text{len}(A) == 1$  then  
    return  $A$   
  else  
     $x \leftarrow A$   
     $A_l \leftarrow \{a \in A : a < x\}$   
     $A_h \leftarrow \{a \in A : a >$   
 $x\}$   
     $A_x \leftarrow \{a \in A : a =$   
 $x\}$   
     $S_l \leftarrow \text{QuickSort}(A_l)$   
     $S_h \leftarrow \text{QuickSort}(A_h)$   
    return  $[S_l, A_x, S_h]$   
  end if  
end procedure
```

What if we can choose the  
**median element** of  $A$ ?

# Quicksort: a Recursion Example

```
procedure QUICKSORT( $A$ )

# Other types of complexity

- ▶ Complexity questions are primarily asked about:
  - ▶ **Computation** (time)
  - ▶ **Space** (memory)
  - ▶ **Communication** (data transfer)
- ▶ They are all studied analogously - it is the unit of counting that changes
- ▶ Despite that, the theory is quite different

# Space complexity

- ▶ Simply the amount of memory that an algorithm needs
- ▶ You can calculate it simply by adding the memory allocations
- ▶ Space required is **additional** to the input, which is **not** counted - this can conceptually not be stored at all, as in e.g. streaming algorithms
- ▶ Formally defined in terms of the Turing Machine (8.1.3)
- ▶ It can often be traded for time complexity, e.g. by storing intermediate results vs revisiting the calculation
- ▶ For a Data Scientist, this trade off is critical!
- ▶ We use the same notation

# Space complexity example (1)

- ▶ **Problem:** Find  $x, y$  in  $X$  s.t.  $x + y = T$  (known to exist)
- ▶ Solution 1:

```
import heapq
heapq.heapsort(X)
i=0; j=n-1;
while(X[i]+X[j]!=T):
    if X[i]+X[j]<T:
        i=i+1
    else:
        j=j-1
```

- ▶ Heapsort has  $\mathcal{O}(1)$  space complexity
- ▶ Therefore the whole algorithm is  $\mathcal{O}(1)$  in space
- ▶ And time complexity  $\mathcal{O}(n \log(n) + n) = \mathcal{O}(n \log(n))$

## Space complexity example (2)

- ▶ Find  $x, y$  in  $X$  s.t.  $x + y = T$  (known to exist)
- ▶ Solution 2:

```
D={}
for i in range(len(X)):
    D[T-X[i]]=i
for x in X:
    y=T-x
    if y in D:
        return X[D[y]],x
```

- ▶ This is  $\mathcal{O}(n)$  in space
- ▶ Hash lookups are  $\mathcal{O}(1)$  **average case** complexity ( $\mathcal{O}(n)$  worst case - which does not apply here!)
- ▶ So this algorithm is  $\mathcal{O}(n)$  in time too

# Communication Complexity

- ▶ Alice knows  $x \in X$ , Bob knows  $y \in Y$
- ▶ Together they want to compute  $f(x, y)$  where  $f \in X \times Y \rightarrow Z$
- ▶ Via a pre-arranged **protocol**  $P$  determining what they send
- ▶ The **communication cost** is the number of bits sent <sup>2</sup>

---

<sup>2</sup>According to Arora and Barak **Computational Complexity: A Modern Approach**. Hopcroft and Ullman **Introduction to Automata Theory, Languages, and Computation** use a 7-tuple. <sup>2</sup>

# Communication Complexity

- ▶ The **Overall cost** of  $P$  is  $C(P) = \max_{x,y}[P(x,y)]$ , i.e. the maximum possible cost for all data
- ▶ The **Communication complexity** of  $f$  is  $C(f) = \min_{P \in \mathcal{P}}(C[P(x,y)])$
- ▶ It is the minimum number of bits needed to compute  $f(x,y)$  for any  $x,y$
- ▶ Communication Complexity Theory describes  $C(f)$ , typically by finding **bounds** (upper and lower) for a given  $f$ 
  - ▶ Again typically as a function of the size of  $x$  and  $y$ , and always for some well defined spaces  $X$  and  $Y$ .
- ▶ Note that there is a trivial bound of  $n + 1$  for transferring all the data! (and then the answer back)

# Communication Complexity Examples

- ▶  $f(x, y) = \text{Parity}([x, y])$ 
  - ▶  $\text{Parity} = \text{mod}_2(\sum_{i=1}^n x_i)$
  - ▶  $C(f(x, y)) = 2$  because Alice calculates the Parity of  $x$ , Bob the Parity of  $y$ , and they each communicate their own parity
- ▶  $f(x, y) = \text{Equality}(x, y)$ 
  - ▶ i.e. 1 if  $x_i = y_i \quad \forall i$ , and 0 otherwise
  - ▶  $C(f(x, y)) = n$  because every bit must be compared
- ▶ Typically approximate algorithms allow dramatically lower complexity
  - ▶ All the interesting theory is in this space

# What is communication complexity theory good for?

- ▶ There are lots of immediate applications
  - ▶ Optimisation of computer networks
  - ▶ **Parallel algorithms**: communication between multiple cores on a CPU, or nodes of a cluster
  - ▶ And basically anything involving the internet!
  - ▶ Especially differential privacy (Block 12)
- ▶ There are many more less immediate applications
  - ▶ Particularly as a tool for algorithm and data structure lower bounds

# The Universal Turing Machine

Turing machines

# High level description

- ▶ Consider a function  $f(\{x\}^d)$  where  $\{x\}^d$  is a string of  $d$  bits (0 or 1)
- ▶ An algorithm for computing  $f$  is a set of rules such that we compute  $f$  for any  $\{x\}^d$
- ▶  $d$  is arbitrary
- ▶ The set of rules is fixed
- ▶ But can be arbitrarily complex and applied arbitrarily many times
- ▶ Rules are made up of **elementary operations**:
  1. Read a symbol of input
  2. Read a symbol from a “memory”
  3. Based on these, write a symbol to the “memory”
  4. Either stop and output TRUE, FALSE, or choose a new rule

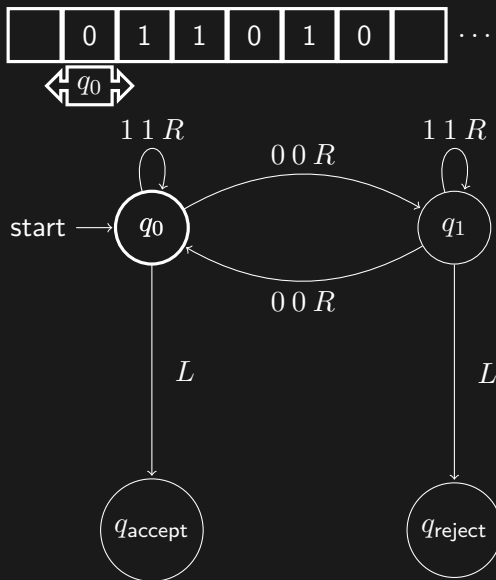

# Formal description

- ▶ A **Turing Machine** is a 3-tuple<sup>3</sup>  $(Q, \Gamma, \delta)$ :
- ▶ where  $Q, \Gamma$  are finite sets and:
  - ▶  $Q$  is the set of all states, containing special states:
    - ▶  $q_0 \in Q$  is the start state
    - ▶  $q_{\text{accept}} \in Q$  is a set of accept states
    - ▶  $q_{\text{reject}} \in Q$  is a set of reject state where  $q_{\text{accept}} \neq q_{\text{reject}}$
  - ▶  $\Gamma$  is the tape (“memory”) alphabet with  $\sqcup \in \Gamma$ . The input space is  $\Sigma \subset \Gamma$  excluding  $\sqcup$  (the blank space).
  - ▶  $\delta : Q \times \Gamma \rightarrow Q \times \Gamma \times \{L, R\}$  is a transition function.

---

# Turing Machine Example

# Turing Machine Example

# Turing Machine Example

# Turing Machine Example

# Turing Machine Example

# Turing Machine Example

# Turing Machine Example

# Turing Machine Example

# Turing Machine Equivalence

- ▶ Turing Machines with the following properties are all equivalent:
  - ▶ A binary only alphabet
  - ▶ Multiple tapes
  - ▶ A doubly infinite tape
  - ▶ Designated input and/or output tapes
  - ▶ Universal Turing Machines

# Conceptual objects in algorithms

- ▶ We have now met at least the following classes of object:
  1. **Functions**, which are conceptual mathematical objects
  2. **Algorithms**, which are implementations that compute a function, comprising:
    - a. **Pseudocode**, which are human-readable algorithms (though can still be precise)
    - b. **Computer code**, which is a machine-readable algorithm,
    - c. **Turing machines programmes**, which are mathematical representations of an algorithm.
- ▶ It takes proof to establish equivalence between classes of Algorithm
  - ▶ This is important for guaranteeing algorithms give the correct output
  - ▶ However, it has been proven that the correspondance between these exists.

# Using Turing Machines

- ▶ Turing Machines are a tool for proving properties of Algorithms.
  - ▶ A wide class of computer architectures map to a Turing Machine
  - ▶ This allows proofs to **ignore implementation details**
  - ▶ For example: Programming language and CPU Chipset do not matter (Finiteness excepting)
- ▶ We will not use Turing Machines in proofs!
- ▶ What you need to know:
  - ▶ High level description of the Turing Machine
  - ▶ That it is used to make algorithmic proofs by connecting a Turing Machine to a particular algorithm
  - ▶ They enable a wide class of otherwise disparate computer architectures to be mapped and shown to be equivalent

# Complexity Classes

- ▶ We often do not care about the details of a certain function
- ▶ We instead ask, “Is this function in a certain complexity class?”

# Polynomial Time: P

- ▶ An algorithm with time complexity  $T(n)$  runs in **Polynomial Time** if  $T(n) \in \cup_{i=1}^{\infty} \mathcal{O}(n^i)$ .
- ▶ A language  $L \in \mathbf{P}$  if there exists a Turing machine  $M$  such that:
  - ▶  $M$  runs in polynomial time for all inputs
  - ▶  $\forall x \in L : M(x) = 1$
  - ▶  $\forall x \notin L : M(x) = 0$

# Examples of algorithms in P

- ▶ **Primality Testing**: is a number  $x$  a prime number?
- ▶ **Shortest Path** in a graph: given two nodes, what is the shortest path? (for example, **Dijkstra's Algorithm**)
- ▶ **Minimal Weighted Matching**: Given  $n$  jobs on  $n$  machines with cost matrix  $c_{ij}$ , how do we allocate jobs? Solvable as an **integer program**.
- ▶ **Pattern Matching**: Asking, is a given **pattern present** in the data? The runtime depends on the data structure and pattern, but broad classes are solvable (e.g. **graphs**)

# Non-Determinism

- ▶ A **Non-Deterministic** Turing machine is like a Turing Machine, except  $\delta$  can go to multiple states for the same input.
- ▶ When a choice of transition is given, the Non-Deterministic Turing Machine “takes them all simultaneously”.
- ▶ The machine accepts if any of the paths accept.

# Non-Deterministic Polynomial Time: NP

- ▶ A language  $L \in \text{NP}$  if there exists a **Non-Deterministic** Turing machine  $M$  such that:
  - ▶  $M$  runs in **Polynomial Time** for all inputs
  - ▶  $\forall x \in L : M(x) = 1$
  - ▶  $\forall x \notin L : M(x) = 0$

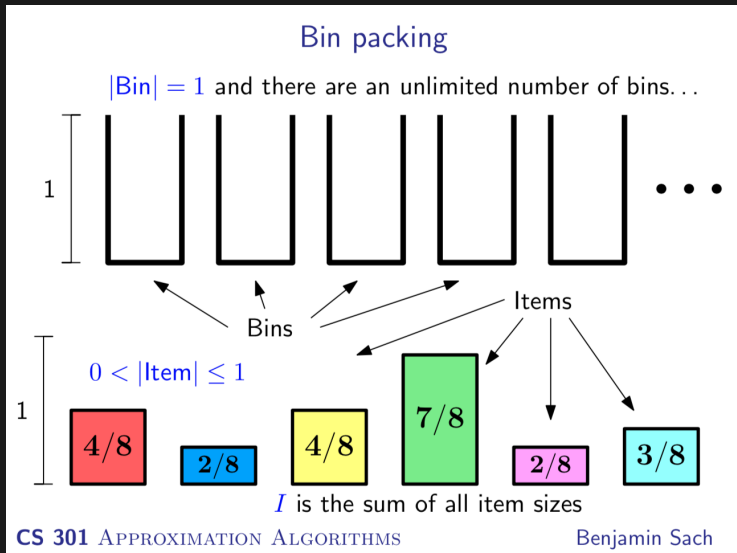

# Examples of algorithms in NP

- ▶ **Travelling salesman problem**: Given a distance matrix between  $n$  cities, is there a route between them all with total distance less than  $D$ ?
- ▶ **Bin packing**: Can you place  $n$  items into as few fixed-size bins as possible?
- ▶ **Boolean satisfiability**: Is a set of boolean logic statements true?
- ▶ **Integer factorisation**: Given a number  $x$ , what are its primes?

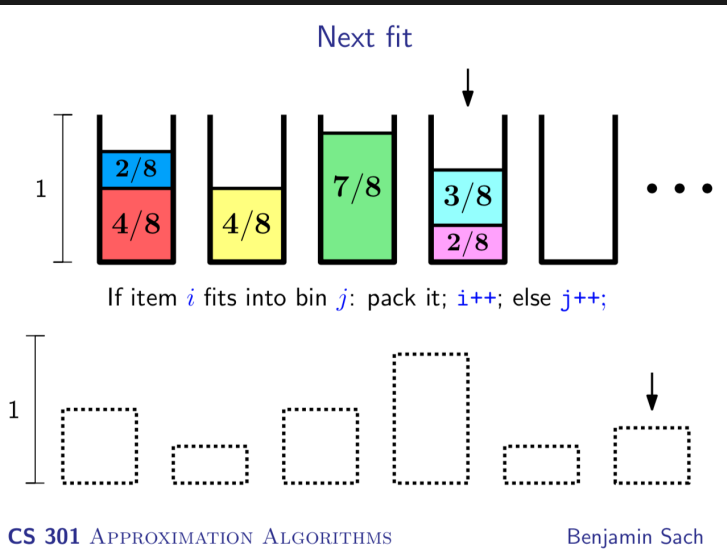

# Data science consequences

- ▶ Having an algorithm is the easiest way to prove that  $f$  is in a complexity class.
  - ▶ It is hard to prove that a problem is not in P!
- ▶ Many exact problems seem to be NP.
- ▶ We can sometimes do very well with an **approximate algorithm** in P. Examples:
  - ▶ Travelling salesman: exactly solved for Euclidean distances, Christofides and Serdyukov's approximation using minimum weight perfect matching
  - ▶ Bin packing. . .
- ▶ Quantifying approximation error is therefore very important!

# Bin packing problem

# Bin packing: next fit

# Bin packing: next fit

## Next fit

Next fit runs in  $O(n)$  time but how good is it?

- Let  $\text{fill}(i)$  be the sum of item sizes in bin  $i$   
and  $b$  the number of non-empty bins (using Next fit)
- Observe that  $\text{fill}(2i-1) + \text{fill}(2i) > 1$  (for  $1 \leq 2i \leq b$ )

$$\text{so } \lfloor b/2 \rfloor < \sum_{1 \leq 2i \leq b} \text{fill}(2i-1) + \text{fill}(2i) \leq I \leq \text{Opt}$$

Next fit is an 2-approximation for bin packing which runs in linear time

# Bin packing: first fit decreasing

## First fit decreasing (FFD)

Step 1: Sort the items into non-increasing order

Step 2: Put each item in the first (left-most) bin it fits in

# Bin packing: first fit decreasing

## First fit decreasing (FFD)

- Consider bin  $j = \lceil \frac{2b}{3} \rceil$  (FFD uses  $b$  bins on this instance)

Case 2: Bin  $j$  contains only items of size  $\leq 1/2$

As  $\lceil 2k/3 \rceil - 1 < I$

we have that  $\lceil 2k/3 \rceil - 1 \leq 2k/3 \leq \text{Opt}$

- So FFD is a  $3/2$ -approximation for bin packing

# Addendum

- ▶ Complexity classes are not everything!
- ▶ Some examples of algorithms in  $P^4$ :
  - ▶ Max-Bisection is approximable to within a factor of 0.8776 in around  $O(n^{10^{100}})$  time
  - ▶ Energy-driven linkage unfolding algorithm is at most  $117607251220365312000n^{79}(l_{max}/d_{min}(\Theta_0))^{26}$
  - ▶ The classic “picture dropping problem” for how to wrap string such that it that will drop when one nail is removed, with  $n$  nails, can be solved in  $O(n^{43737})$
  - ▶ Approximate algorithms (accurate to within  $(1 + \epsilon)$  often scale badly, e.g.  $O(n^{1/\epsilon})$

---

<sup>4</sup>Stack Exchange **Polynomial Time algorithms with huge exponent**

# Wrapup

- ▶ Complexity classes are important
- ▶ They apply to space, time, communication, memory
- ▶ Often we require approximate algorithms:
  - ▶ with better complexity
  - ▶ and quantifiable performance degradation
- ▶ However, empirical performance does not always match asymptotic complexity
